### Summary

This study aimed to investigate the vasoactivity of sulfur dioxide (SO<sub>2</sub>), a novel gas identified from vascular tissue, in rat thoracic aorta. The thoracic aorta was isolated, cut into rings, and mounted in organ-bath chambers. After equilibrium, the rings were gradually stretched to a resting tension. Isometric tension was recorded under the treatments with vasoconstrictors, SO<sub>2</sub> derivatives, and various drugs as pharmacological interventions. In endothelium-intact aortic rings constricted by 1 μM phenylephrine (PE), SO<sub>2</sub> derivatives (0.5 – 8 mM) caused a dose-dependent relaxation. Endothelium removal and a NOS inhibitor L-NAME reduced the relaxation to low doses of SO<sub>2</sub> derivatives, but not that to relatively high doses (≥ 2 mM). In endothelium-denuded rings, SO<sub>2</sub> derivatives attenuated vasoconstriction induced by high K<sup>+</sup> (60 mM) or CaCl<sub>2</sub> (0.01-10 mM). The relaxation to SO<sub>2</sub> derivatives in PE-constricted rings without endothelium was significantly inhibited by blockers of ATP-sensitive K<sup>+</sup> (K<sub>ATP</sub>) and Ca<sup>2+</sup>-activated K<sup>+</sup> (K<sub>Ca</sub>) channels, but not by those of voltage-dependent K<sup>+</sup> channels, Na<sup>+</sup>-K<sup>+</sup>-ATPase or Na<sup>+</sup>-Ca<sup>2+</sup> exchanger. SO<sub>2</sub> relaxed vessel tone via endothelium-dependent mechanisms associated with NOS activation, and via endothelium-independent mechanisms dependent on the inhibition of voltage-gated Ca<sup>2+</sup> channels, and the opening of K<sub>ATP</sub> and K<sub>Ca</sub> channels.

### Introduction

The vascular endothelium has been established as an abundant source of vasoactive substances including gases, such as nitric oxide (NO), carbon oxide (CO) and sulfureted hydrogen (H<sub>2</sub>S) (Bhatia 2005). Sulfur dioxide (SO<sub>2</sub>) is a novel gas first detected in porcine coronary artery by Balazy *et al.* (2003). A possible precursor of SO<sub>2</sub> could be the intracellular thiol such as cysteine that can be oxidized to cysteinesulfenic acid by cysteine dioxygenase. Cysteinesulfinate can further be transformed by glutamate-oxaloacetate transaminase to generate β-sulfinylpyruvate, which decomposes spontaneously to pyruvate and SO<sub>2</sub> (Griffith 1983). Another pathway that can produce SO<sub>2</sub> is the oxidation of H<sub>2</sub>S by NADPH oxidase (Mitsuhashi *et al.* 2005).

Little is known about the vasoactivity of SO<sub>2</sub>. A few studies addressed the systemic impact of SO<sub>2</sub> inhalation under the concern that SO<sub>2</sub> is a common air pollutant. Meng *et al.* (2003) reported that both SO<sub>2</sub> inhalation and intraperitoneal injection of SO<sub>2</sub>

derivatives decreased blood pressure in rats, implying possible vasorelaxant activity of SO<sub>2</sub>. Besides, ACh was shown to stimulate the formation of SO<sub>2</sub> (Balazy *et al.* 2003), raising a possibility that SO<sub>2</sub> is involved in the profound vasodilation response to ACh. However, the direct vasoactivity of SO<sub>2</sub> has never been described.

SO<sub>2</sub> is quite soluble in water. Upon solution, it hydrates rapidly to form sulfurous acid, which dissociates in turn to form sulfite and bisulfite ions (3:1 M/M, in neutral fluid) (Shapiro 1977). The present study observed that SO<sub>2</sub> derivatives, a mixture of sulfite and bisulfite (Na<sub>2</sub>SO<sub>3</sub>/NaHSO<sub>3</sub>) in a molar ratio of 3:1, elicited potent vasorelaxation in isolated rat aortic rings constricted by phenylephrine (PE) through both endothelium-dependent and -independent mechanisms. The endothelium-dependent relaxation induced by SO<sub>2</sub> was revealed by denuding the endothelium and applying a NOS inhibitor N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME), and the endothelium-independent mechanism was further investigated by using a variety of ion channel interventions such as antagonist of K<sup>+</sup> channels, voltage-gated Ca<sup>2+</sup> channels, Na<sup>+</sup>-K<sup>+</sup> pump and Na<sup>+</sup>-Ca<sup>2+</sup> exchange in endothelium-denuded aortic rings.

## Materials and Methods

### Preparation of rat aortic rings

This study was performed in accordance with the Guide for Care and Use of Laboratory Animals published by the U.S. National Academy Press in 1996 and the Guidelines for Animal Experiments of the Second Military Medical University, China.

Male Sprague-Dawley rats (250-350 g) were anesthetized by intraperitoneal injection of 1 g/kg urethane with 750 U heparin. The thoracic aorta was quickly removed, cleaned of all connective and fat tissue, and cut into rings of 3 mm in length. The aortic rings were then mounted in organ-bath chambers containing modified Krebs-Henseleit (K-H) solution (pH 7.4) at 37 °C, continuously bubbled with 95 % O<sub>2</sub> – 5 % CO<sub>2</sub>. The modified K-H solution contained (in mM): NaCl 118, KCl 4.6, MgSO<sub>4</sub> 1.2, KH<sub>2</sub>PO<sub>4</sub> 1.2, glucose 11.1, NaHCO<sub>3</sub> 27.2, EGTA 0.03, CaCl<sub>2</sub> 1.8. After 30-min equilibrium, the rings were gradually stretched to a resting tension of 2 g over 40 min. Isometric tension was recorded with force displacement transducers coupled to a computerized recording system (Nanjing MedEase Science and Technology Co. LTD, Nanjing, China).

### Protocols

After two challenges with 60 mM KCl, aortic rings were constricted by 1 μM phenylephrine (PE) and subsequently challenged with 1 μM acetylcholine (ACh) to confirm the integrity or removal of the endothelium. Then they were washed in K-H solution to restore tension to baseline level and allowed to stabilize for 60-90 min. The rings were constricted submaximally by 1 μM phenylephrine (PE) again, and SO<sub>2</sub> derivatives (Na<sub>2</sub>SO<sub>3</sub> and NaHSO<sub>3</sub>, 3:1 M/M) were added cumulatively into the bathing solution once steady contraction was obtained. The equivalent SO<sub>2</sub> concentration ranged from 0.5 to 8 mM. We have examined the pH of the Krebs solution that it is about 7.40 under normal conditions. After we add SO<sub>2</sub> derivatives at the lower concentrations (0.5~2 mM), the pH does not change. It will decrease to 7.37 after SO<sub>2</sub> derivatives added at the higher concentrations (4~8 mM) and can return to 7.40 in 3-4 min. Relaxation was calculated as a percentage of the maximal tension induced by PE (Engler *et al.* 2000).

The role of endothelium/nitric oxide (NO) in vasorelaxant responses to SO<sub>2</sub> derivatives was first examined. For this set of experiments, the endothelium was removed mechanically by gently rubbing the luminal surface of aortic rings with a wire, and the functional removal was confirmed by the lack of relaxation in response to ACh as aforementioned. To examine the involvement of NO, endothelium-intact rings were exposed for 30 min to a non-specific NOS inhibitor L-NAME (N<sup>G</sup>-nitro-L-arginine methyl ester, 100 μM) before the addition of PE.

To study the participation of K<sup>+</sup> channels in endothelium-independent relaxation induced by SO<sub>2</sub> derivatives, aortic rings without endothelium were constricted with high K<sup>+</sup> (60 mM, to abolish the effect of K<sup>+</sup> channel activation) (Sang *et al.* 2003), and SO<sub>2</sub> derivatives were applied cumulatively. To further identify the types of K<sup>+</sup> channels associated with SO<sub>2</sub>, a K<sub>ATP</sub> blocker glibenclamide (3 μM), a K<sub>Ca</sub> blocker tetraethylammonium chloride (TEA, 5 mM) or a K<sub>V</sub> blocker 4-aminopyridine (4-AP, 100 μM) were applied to endothelium-denuded rings 30 min prior to the addition of PE. Only one concentration-response curve to SO<sub>2</sub> derivatives was obtained per ring in the presence of each inhibitor.

The ability of SO<sub>2</sub> to modulate Ca<sup>2+</sup> influx *via* VGCCs was studied using CaCl<sub>2</sub>-constricted rings without endothelium, as described previously (Chan *et al.* 2005). For this set of experiments, two consecutive

concentration-dependent constrictions to  $\text{CaCl}_2$  were obtained in the absence and in the presence of  $\text{SO}_2$  derivatives (0.5–8 mM, 5-min incubation). For constructing  $\text{CaCl}_2$  concentration-response curve, arterial rings were rinsed three times in  $\text{Ca}^{2+}$ -free solution containing 30 mM  $\text{Na}_2\text{-EGTA}$  and then incubated in  $\text{Ca}^{2+}$ -free, 60 mM  $\text{K}^+$  solution before the cumulative addition of  $\text{CaCl}_2$  (0.01–10 mM). The effect of 1  $\mu\text{M}$  nifedipine was tested as control.

In the final set of experiments, the rings were constricted with 1  $\mu\text{M}$  PE and relaxed with cumulative  $\text{SO}_2$  derivatives (0.5–8 mM).  $\text{Na}^+\text{-K}^+\text{-ATPase}$  inhibitor ouabain (100 mM) or  $\text{Na}^+\text{-Ca}^{2+}$  exchanger inhibitor nickel chloride (30  $\mu\text{M}$ ) was applied 30 min prior to the addition of PE.

### Drugs

All the drugs were purchased from Sigma-Aldrich (St Louis, MO, USA). They were dissolved in K-H solution except for glibenclamide, which was dissolved in dimethyl sulfoxide first and diluted with K-H solution before use. The final content of dimethyl sulfoxide was 0.2 % (v/v), which did not affect vessel tension.

### Statistical analyses

All data are presented as means  $\pm$  S.E.M.  $\text{SO}_2$ -induced relaxation is expressed as the percentage change from the PE-contracted levels of tension. One-way repeated-measures ANOVA was used for comparisons of concentration-response curves. One-way ANOVA was used for comparisons at each drug concentration.  $P < 0.05$  value was considered significant.

## Results

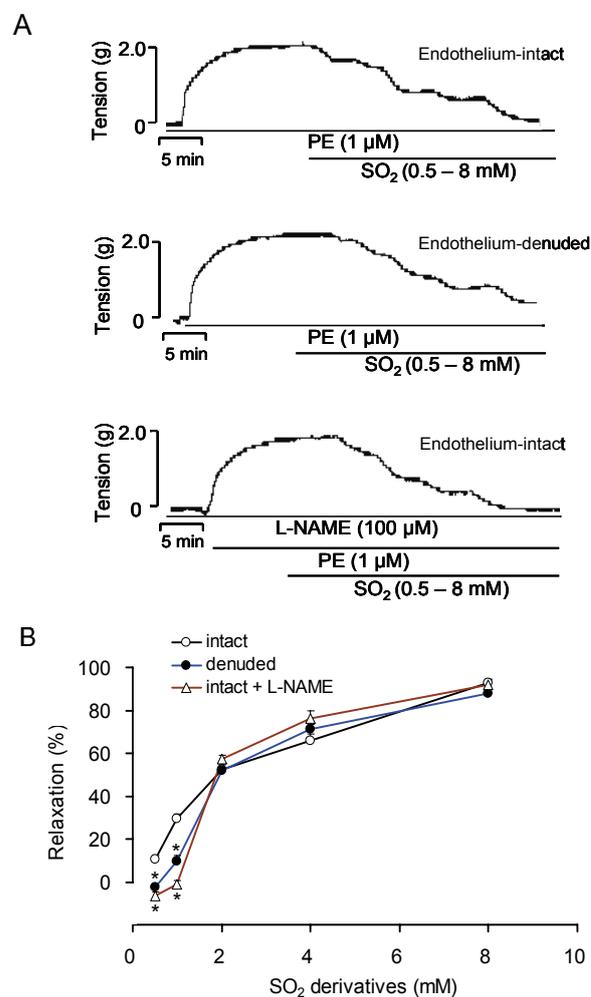

### $\text{SO}_2$ derivatives relaxed aortic rings by endothelium-dependent and -independent mechanisms

The thoracic aortic rings were equilibrated for 60–90 min at the optimal preload of 2 g, and then cumulative concentrations of  $\text{SO}_2$  derivatives (0.5, 1, 2, 4, 8 mM) were administered. No relaxation or constriction was observed (data not shown).

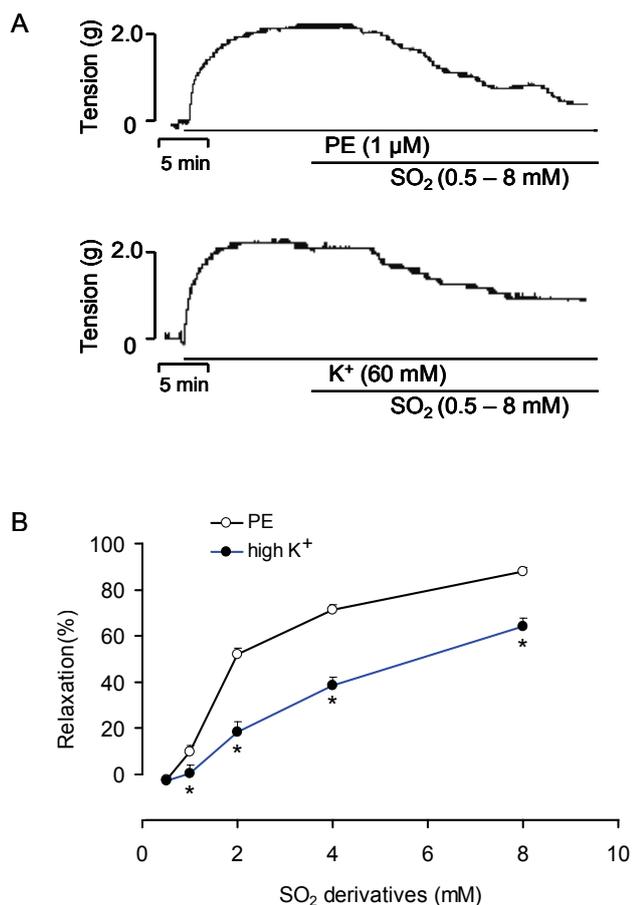

The vasoconstriction induced by 1  $\mu\text{M}$  PE was progressively relaxed by cumulative  $\text{SO}_2$  derivatives (0.5–8 mM) in both endothelium-intact and -denuded rings. Figure 1A shows representative recordings. Lower concentrations of  $\text{SO}_2$  derivatives (0.5 and 1 mM) caused less relaxation in endothelium-denuded rings than that in

endothelium-intact rings ( $P < 0.01$ , Fig. 1B). However, relatively higher concentrations of  $\text{SO}_2$  derivatives (2, 4 and 8 mM) relaxed the rings with and without endothelium to the same extent (Fig. 1B). These data suggest that both endothelium-dependent and -independent relaxations are induced by  $\text{SO}_2$  derivatives at lower doses, while the endothelium-independent relaxation is predominantly displayed at higher doses.

In agreement with the phenomenon, a non-selective NOS inhibitor L-NAME (100  $\mu\text{M}$ ) abolished the relaxation of endothelium-intact rings induced by lower doses of  $\text{SO}_2$  derivatives (0.5 and 1 mM), but failed to affect that by higher doses (Fig. 1). It is suggested that NOS pathway is involved in the endothelium-dependent relaxation induced by  $\text{SO}_2$  derivatives.

**Fig. 1.** Relaxation to  $\text{SO}_2$  derivatives (0.5–8 mM) in rat thoracic aortic rings pre-constricted by 1  $\mu\text{M}$  phenylephrine (PE). (A) Representative traces of vessel tension in response to PE and cumulative  $\text{SO}_2$  derivatives; (B) Relaxation curves in (○) endothelium-intact rings ( $n = 18$ ), (●) endothelium-denuded rings ( $n = 18$ ), and (△) endothelium-intact rings treated with 100  $\mu\text{M}$  of a non-specific NOS inhibitor L-NAME ( $n = 8$ ). Results are mean  $\pm$  S.E.M. \* $P < 0.01$  vs. endothelium-intact rings.

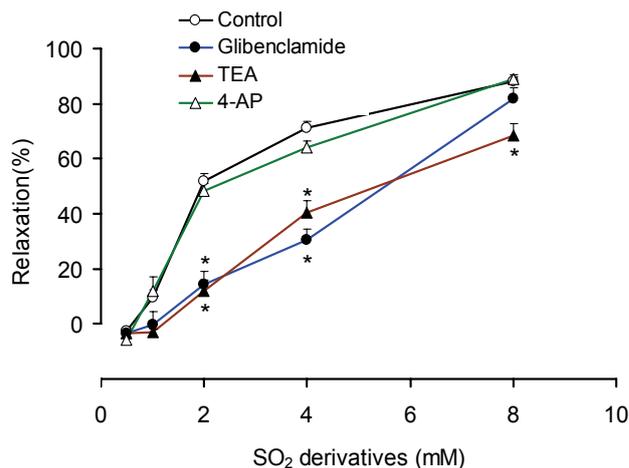

**Fig. 2.** Relaxation to SO<sub>2</sub> derivatives (0.5–8 mM) in endothelium-denuded aortic rings precontracted by 1 μM phenylephrine (PE, n = 18) or 60 mM K<sup>+</sup> (high K<sup>+</sup>, n = 8). **(A)** Representative traces of vessel tension; **(B)** Relaxation curves in rings precontracted by 1 μM phenylephrine (PE, ○) or 60 mM K<sup>+</sup> (high K<sup>+</sup>, ●). Results are mean ± S.E.M. \* P < 0.01 vs. PE.

#### Ion channels involved in endothelium-independent relaxation induced by SO<sub>2</sub> derivatives

##### Involvement of K<sup>+</sup> channels

In endothelium-denuded aortic rings constricted with 1 μM PE, SO<sub>2</sub> derivatives caused a dose-dependent relaxation with the maximum of 87.99 ± 1.82 % at 8 mM (Fig. 2A). In the rings constricted with high K<sup>+</sup> (60 mM), however, the relaxation to SO<sub>2</sub> derivatives was significantly inhibited (maximum 63.88 ± 3.78 %, P < 0.01, Fig. 2B), though the contraction induced by high K<sup>+</sup> was comparable to that by PE (data not shown). On the one hand, the lessened vasorelaxant activity of SO<sub>2</sub> derivatives suggests that the opening of K<sup>+</sup> channels contributes to the relaxation, since high K<sup>+</sup> is presumed to block all K<sup>+</sup> channels (Sang *et al.* 2003). On the other hand, the persistent existence of vasorelaxation in response to SO<sub>2</sub> derivatives under high-K<sup>+</sup> conditions suggests that K<sup>+</sup> channel-independent mechanisms also

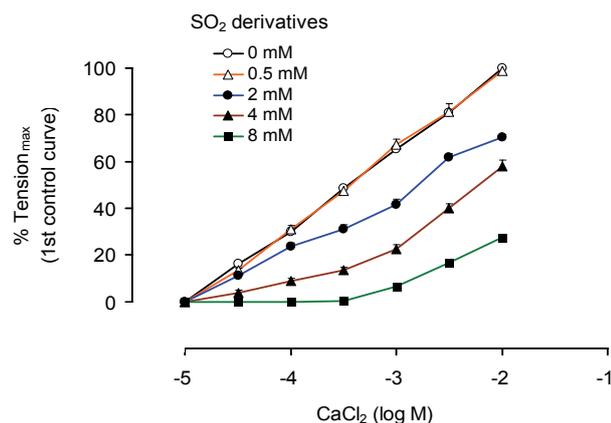

**Fig. 3.** Relaxation to SO<sub>2</sub> derivatives (0.5–8 mM) in endothelium-denuded aortic rings precontracted by 1 μM PE. Glibenclamide (3 μM, n = 10), TEA (5 mM, n = 15) or 4-AP (100 μM, n = 12) were incubated for 30 min before the addition of PE. Results are mean ± S.E.M. \* P < 0.01 vs. control.

contribute to the relaxation.

To further identify the types of K<sup>+</sup> channels involved in SO<sub>2</sub>-induced relaxation, aortic rings without endothelium were treated with glibenclamide (3 μM), TEA (5 mM) and 4-AP (100 μM) to block K<sub>ATP</sub>, K<sub>Ca</sub> and K<sub>V</sub>, respectively. The vasoconstriction induced by PE remained unchanged by the presence of glibenclamide, TEA or 4-AP. As shown in Figure 3, glibenclamide significantly reduced the relaxation caused by 4 mM and 2 mM SO<sub>2</sub> derivatives from 71.06 ± 2.42 to 30.54 ± 4.05 % (P < 0.01), and from 51.77 ± 2.77 to 14.44 ± 4.63 % (P < 0.01), respectively. Similarly, TEA significantly reduced the relaxation resulting from 4 mM and 2 mM SO<sub>2</sub> derivatives to 40.36 ± 4.22 % (P < 0.01) and 11.97 ± 4.14 % (P < 0.01), respectively. Besides, the relaxant response to 8 mM SO<sub>2</sub> derivatives was also significantly reduced by TEA (68.62 ± 4.27 % vs. 87.99 ± 1.82 %, P < 0.01). However, 4-AP did not affect the relaxation (n = 12, P > 0.05 vs. control). These data indicate that SO<sub>2</sub>-induced relaxation is associated with the opening of K<sub>ATP</sub> and K<sub>Ca</sub> channels in smooth muscle cells, but not K<sub>V</sub> channels.

##### Involvement of voltage-gated Ca<sup>2+</sup> channels

In Ca<sup>2+</sup>-free, 60 mM K<sup>+</sup> solution, cumulative CaCl<sub>2</sub> (0.01–10 mM) induced progressive constriction of aortic rings without endothelium. The maximal tension was approximately 2.5 g. SO<sub>2</sub> derivatives (0.5–8 mM) reduced CaCl<sub>2</sub>-induced constriction in a dose-dependent manner with progressive suppression of the maximal constriction (n ≥ 6 for each group, Fig. 4). In control

**Fig. 4.**  $\text{CaCl}_2$ -induced contraction in  $\text{Ca}^{2+}$ -free, 60 mM  $\text{K}^+$  solution in the absence and presence of  $\text{SO}_2$  derivatives (0.5–8 mM) in aortic rings without endothelium. Results are mean  $\pm$  S.E.M. of eight experiments.

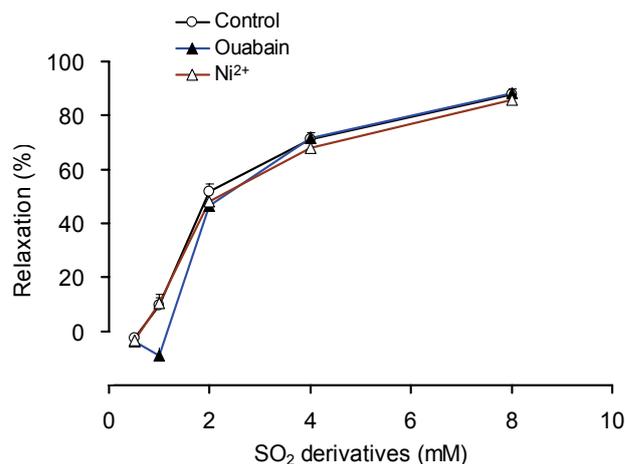

experiments, 1  $\mu\text{M}$  nifedipine abolished vasoconstriction to  $\text{CaCl}_2$  (data not shown).

#### No involvement of $\text{Na}^+/\text{K}^+$ pump and $\text{Na}^+/\text{Ca}^{2+}$ exchanger

Increased activity of  $\text{Na}^+/\text{K}^+$  pump results in a reduction in  $[\text{Na}^+]_i$ , which may stimulate the forward mode of  $\text{Na}^+/\text{Ca}^{2+}$  exchanger and facilitate muscle relaxation. To test whether  $\text{SO}_2$ -induced vasodilation is associated with the stimulation of  $\text{Na}^+/\text{K}^+$  pump or forward  $\text{Na}^+/\text{Ca}^{2+}$  exchanger, the present study used a  $\text{Na}^+/\text{K}^+$ -ATPase inhibitor ouabain (100  $\mu\text{M}$ ) and a putative  $\text{Na}^+/\text{Ca}^{2+}$  exchanger inhibitor  $\text{Ni}^{2+}$  (30  $\mu\text{M}$ ). Neither ouabain nor  $\text{Ni}^{2+}$  affected the vasodilation resulting from  $\text{SO}_2$  derivatives in PE-constricted aortic rings without endothelium (Fig. 5). It is suggested that  $\text{Na}^+/\text{K}^+$  pump and  $\text{Na}^+/\text{Ca}^{2+}$  exchanger are not involved in the vasorelaxant response to  $\text{SO}_2$  derivatives.

## Discussion

The vasoactivity of  $\text{SO}_2$  has never been described before, although it was found in vascular tissue (Balazy *et al.* 2003). The present study first revealed the direct vasorelaxant activity of  $\text{SO}_2$ . In constricted rat aortic rings under isometric recording, we found that the derivatives of  $\text{SO}_2$  hydration, sulfite and hydrogen sulfite (Shapiro 1977), reduced vessel tension in a dose-dependent manner. The vasorelaxation resulting from low doses of  $\text{SO}_2$  derivatives (0.5 and 1 mM) was attenuated by endothelium removal and a non-specific NOS inhibitor L-NAME (Fig. 1), indicating the involvement of

**Fig. 5.** Relaxation to  $\text{SO}_2$  derivatives (0.5–8 mM) in endothelium-denuded aortic rings pre-constricted by 1  $\mu\text{M}$  phenylephrine (PE). Rings were incubated with 100 mM ouabain ( $n = 14$ ) or 30  $\mu\text{M}$   $\text{NiCl}_2$  ( $n = 13$ ) for 30 min before the addition of PE. Results are mean  $\pm$  S.E.M.

endothelium-dependent mechanisms associated with NO. In contrast, the relaxation induced by high doses of  $\text{SO}_2$  derivatives (2–8 mM) was not changed by endothelium removal or NOS inhibition (Fig. 1), suggesting that the endothelium-independent relaxation was predominant in the presence of a relatively large amount of  $\text{SO}_2$ . Previous report showed that the endothelium-independent relaxation by  $\text{SO}_2$  derivatives was not mediated by NO (Meng and Zhang 2007). It is not in agreement with our results and need further research.

We further studied the ion channels involved in the potent endothelium-independent vasodilation induced by  $\text{SO}_2$  derivatives, using pharmacological interventions. It is well known that  $\text{K}^+$  plays a vital role in regulating muscle contractility and vascular tone (Nelson *et al.* 1995). A rise in  $\text{K}^+$  permeability normally hyperpolarizes cell membrane and thus inhibits  $\text{Ca}^{2+}$  influx through VGCCs, resulting in muscle relaxation. To test whether or not  $\text{SO}_2$  can increase  $\text{K}^+$  permeability, we observed the relaxant response to  $\text{SO}_2$  derivatives in endothelium-denuded rings challenged with high  $\text{K}^+$  (60 mM), a putative blocker for all  $\text{K}^+$  channels (Sang *et al.* 2003). The vessel tone caused by high  $\text{K}^+$  (60 mM) was comparable to that by PE (1  $\mu\text{M}$ ). However, the relaxant response to  $\text{SO}_2$  derivatives was smaller in rings receiving  $\text{K}^+$  than those receiving PE, suggesting that  $\text{SO}_2$  derivatives activated  $\text{K}^+$  channels. Balazy *et al.* (2003) proposed  $\text{SO}_2$  as a candidate for the unidentified endothelium-derived hyperpolarizing factor (EDHF), based on the facts that of  $\text{SO}_2$  has a short-life comparable to EDHF and the formation of  $\text{SO}_2$  can be stimulated by

ACh (Balazy *et al.* 2003). Here we demonstrate that SO<sub>2</sub> derivatives relax vascular smooth muscle at least partially through opening K<sup>+</sup> channels, a well-characterized property of EDHF, supporting SO<sub>2</sub> as a candidate for EDHF.

Previous report also studied the mechanisms of the endothelium-independent vasodilation induced by SO<sub>2</sub> derivatives and the vasorelaxation was mediated in partly by the inhibition of Ca<sup>2+</sup> channels and the signal transduction pathway of PGI<sub>2</sub>-AC-cAMP-PKA (Meng and Zhang 2007, Meng *et al.* 2007). In the present study, we further investigated the mechanisms of vasodilation induced by SO<sub>2</sub> by using a variety of ion channel interventions such as antagonist of K<sup>+</sup> channels, Na<sup>+</sup>-K<sup>+</sup> pump and Na<sup>+</sup>-Ca<sup>2+</sup> exchange besides voltage-gated Ca<sup>2+</sup> channels. Multiple types of K<sup>+</sup> channels have been identified in vascular smooth muscle cells, among which K<sub>ATP</sub>, K<sub>Ca</sub> and K<sub>V</sub> are relatively predominant (Ferrer *et al.* 1999). To examine their involvement in SO<sub>2</sub>-induced relaxation, glibenclamide, TEA and 4-AP were administered in concentrations tested previously (Bolotina *et al.* 1994, Kitagawa *et al.* 1994, Kitazono *et al.* 1995, Murphy *et al.* 1995, Randall *et al.* 1991) to block K<sub>ATP</sub>, K<sub>Ca</sub> and K<sub>V</sub>, respectively. The relaxation of PE-constricted rings in response to SO<sub>2</sub> derivatives was significantly reduced by glibenclamide and TEA, but not by 4-AP. These findings suggest the involvement of K<sub>ATP</sub> and K<sub>Ca</sub> channels in the vasodilating effect of SO<sub>2</sub>. It is understood that K<sub>ATP</sub> channels play a crucial role under the condition of ischemia and reperfusion, where they are activated to hyperpolarize the membrane and therefore to attenuate injuries. The ability of SO<sub>2</sub> to activate K<sub>ATP</sub> channels indicates a potential protective role of SO<sub>2</sub> in ischemia-reperfusion.

SO<sub>2</sub> derivatives inhibited high K<sup>+</sup>-induced vasoconstriction (Fig. 2A), indicating that SO<sub>2</sub> may act as a Ca<sup>2+</sup> channel inhibitor to cause vascular relaxation. In endothelium-denuded aortic rings, SO<sub>2</sub> derivatives (0.5-8 mM) reduced CaCl<sub>2</sub>-induced constriction in a dose-dependent manner, suggesting that SO<sub>2</sub> derivatives inhibit Ca<sup>2+</sup> influx through VGCCs in smooth muscle

cells. In contrast, the whole cell patch-clamp technique revealed an increased voltage-gated L-type Ca<sup>2+</sup> current under the treatment with SO<sub>2</sub> derivatives in isolated rat ventricular myocytes (Nie *et al.* 2006). It is indicated that SO<sub>2</sub> derivatives may exert different modulations on VGCCs in different cell types.

Sarcolemmal Na<sup>+</sup>-Ca<sup>2+</sup> exchange plays a significant role in regulating [Ca<sup>2+</sup>]<sub>i</sub> in smooth muscle cells and thus vessel tone (Motley *et al.* 1993). The activity of the Na<sup>+</sup>-Ca<sup>2+</sup> exchanger is coupled to [Na<sup>+</sup>]<sub>i</sub>, which is primarily regulated by membrane permeability to Na<sup>+</sup> ions and Na<sup>+</sup>-K<sup>+</sup>-ATPase activity. Decreased permeability to Na<sup>+</sup> or increased activity of Na<sup>+</sup>-K<sup>+</sup> pump results in a reduction in [Na<sup>+</sup>]<sub>i</sub>, which in turn stimulates the forward mode of Na<sup>+</sup>-Ca<sup>2+</sup> exchanger and facilitates vasodilation. Treatment with a Na<sup>+</sup>-K<sup>+</sup>-ATPase inhibitor ouabain or a Na<sup>+</sup>-Ca<sup>2+</sup> exchanger inhibitor Ni<sup>2+</sup> failed to prevent SO<sub>2</sub>-induced relaxation. This phenomenon suggests that the relaxation by SO<sub>2</sub> is unlikely associated with the stimulation of Na<sup>+</sup>-K<sup>+</sup>-ATPase or forward Na<sup>+</sup>-Ca<sup>2+</sup> exchanger.

Altogether, the present study showed that SO<sub>2</sub> derivatives dose-dependently dilated rat aortic rings *via* mechanisms that were both endothelium-dependent and independent. NOS activation contributed to the endothelium-dependent relaxation, and the endothelium-independent relaxation was associated with the activation of K<sub>ATP</sub> and K<sub>Ca</sub>, and the inactivation of VGCCs. In addition, K<sub>V</sub>, Na<sup>+</sup>-K<sup>+</sup>-ATPase and Na<sup>+</sup>-Ca<sup>2+</sup> exchanger were not suggested to be involved in the vasorelaxant response to SO<sub>2</sub> derivatives.
