Summary
Abnormal release of Ca\(^{2+}\) from sarcoplasmic reticulum (SR) via the cardiac ryanodine receptor (RyR2) may contribute to contractile dysfunction in heart failure (HF). We previously demonstrated that RyR2 macromolecular complexes from HF rat were significantly more depleted of FK506 binding protein (FKBP12.6). Here we assessed expression of key Ca\(^{2+}\) handling proteins and measured SR Ca\(^{2+}\) content in control and HF rat myocytes. Direct measurements of SR Ca\(^{2+}\) content in permeabilized cardiac myocytes demonstrated that SR luminal [Ca\(^{2+}\)] is markedly lowered in HF (HF: $\Delta F/F_0 = 26.4 \pm 1.8$, $n=12$; control: $\Delta F/F_0 = 49.2 \pm 2.9$, $n=10$; $P<0.01$). Furthermore, we demonstrated that the expression of RyR2 associated proteins (including calmodulin, sorcin, calsequestrin, protein phosphatase 1, protein phosphatase 2A), Ca\(^{2+}\)ATPase (SERCA2a), PLB phosphorylation at Ser16 (PLB-S16), PLB phosphorylation at Thr17 (PLB-T17), L-type Ca\(^{2+}\) channel (Cav1.2) and Na\(^+\)-Ca\(^{2+}\) exchanger (NCX) were significantly reduced in rat HF. Our results suggest that systolic SR reduced Ca\(^{2+}\) release and diastolic SR Ca\(^{2+}\) leak (due to defective protein-protein interaction between RyR2 and its associated proteins) along with reduced SR Ca\(^{2+}\) uptake (due to down-regulation of SERCA2a, PLB-S16 and PLB-T17), abnormal Ca\(^{2+}\) extrusion (due to down-regulation of NCX) and defective Ca\(^{2+}\)-induced Ca\(^{2+}\) release (due to down-regulation of Cav1.2) could contribute to HF.

Key words
Heart failure • Sarcoplasmic reticulum • Ryanodine receptor

Introduction
Heart failure (HF) is characterized by a complex disorder that leads to a disturbance of the normal pumping of blood to the peripheral organs to meet the metabolic demands of the body. A growing body of evidence has accumulated concerning the altered intracellular Ca\(^{2+}\) cycling that plays a key role in the development of HF (Meyer et al. 1995, Houser and Margulies 2003). Recent advances in the field of molecular biology have shed light on the close relationship between Ca\(^{2+}\) cycling abnormalities and the progression of HF.

The Ca\(^{2+}\) cycle is a definite regulator of myocyte contraction and relaxation. During a normal cardiac cycle, membrane depolarization leads to Ca\(^{2+}\) entry into the cell via L-type Ca\(^{2+}\) channel. The entry of Ca\(^{2+}\), in close proximity to the sarcoplasmic reticulum (SR), triggers a calcium-induced calcium release (CICR) through the SR ryanodine-sensitive receptors (RyRs); Ca\(^{2+}\) diffuses to the myofilaments and activates calcium-sensitive proteins leading to myofilibrillar contraction. The subsequent relaxation is initiated by dissociation of Ca\(^{2+}\) from troponin C, followed by its reuptake into the SR through phospholamban-regulated (PLB-regulated) sarcoplasmic reticulum Ca\(^{2+}\) ATPase (SERCA2a) and subsequent trans-sarcolemmal Ca\(^{2+}\) removal through the Na\(^+\)/Ca\(^{2+}\) exchanger (NCX) operating in its forward mode (Bassani et al. 1994). The whole process of Ca\(^{2+}\) movement is characterized by a transient increase in intracellular [Ca\(^{2+}\)] from 100 nM to about 1µM.

Systolic HF is a disease state associated with weakening of myocardial contractility which ultimately
Hu et al. Vol. 60

results in catastrophic deterioration of ventricular pump function. Although it is clear that reduced SR Ca\textsuperscript{2+} content could lead to reduced systolic Ca\textsuperscript{2+} transients and weakened contractility, the specific mechanisms responsible for the reduced SR Ca\textsuperscript{2+} content in HF remain to be defined. Intracellular free calcium concentration is kept within the physiological limits by maintaining a delicate balance between influx and efflux of Ca\textsuperscript{2+}. Some reports suggest that the reduction of SR Ca\textsuperscript{2+} content has been attributed to depressed SERCA2a function and/or enhanced NCX activity during HF (Shannon et al. 2003). These changes are expected to facilitate Ca\textsuperscript{2+} removal from the cell at the expense of its uptake into the SR and result in under-filled SR Ca\textsuperscript{2+} stores in HF. Another potential cause of reduced SR Ca\textsuperscript{2+} content is enhanced diastolic leak of Ca\textsuperscript{2+} via the RyRs (Marx et al. 2000). Although extensive investigations of both mechanisms have been reported, the results from these studies are not always in agreement. Furthermore, direct experiments concerning the other Ca\textsuperscript{2+} regulatory proteins simultaneously is lacking. Therefore, further studies are needed to determine the mechanisms of altered Ca\textsuperscript{2+} handling in HF.

Here we investigated alternations in SR Ca\textsuperscript{2+} content and the expression of the major Ca\textsuperscript{2+} regulatory proteins. Our aims were to assess: (1) L-type calcium current (LTCC); (2) SR Ca\textsuperscript{2+} content; (3) expression of RyR2 and RyR2 interacting protein, including calmodulin, sorcin, calsequestrin, PP1 and PP2A; (4) expression of SERCA2a, PLB, PLB-S16 and PLB-T17; (5) expression of Cav1.2; and (6) expression of NCX.

Materials and Methods

Surgical procedure and animal models

Animal care and all procedures were approved by the Institutional Animal Care and Use Committee of the Second Military Medical University and were performed in accordance with the “Principles of Laboratory Animal Care by the National Society for Medical Research and the Guide for the Care and Use of Laboratory Animals” (NIH Publication No. 86-23, revised 1985). Adult male Sprague-Dawley (SD) rats (200-250 g) were randomized to receive either myocardial infarction (MI) (Tanonakak 2001) or a sham procedure. Rats were anesthetized by intraperitoneal injection of 10% chloral hydrate (3.5 ml/kg), cannulated, and ventilated with a tidal volume of 1.5-2 ml/100 g (80 strokes/min). A left lateral thoracotomy was performed between the third and fourth ribs, and the left anterior descending (LAD) coronary artery was permanently ligated proximally with a 5-0 silk suture. Sham-operated animal under went the same procedure without ligation of the LAD. The electrocardiogram (ECG) of MI and sham group is clear as shown in Figure 1. The chest was closed, the lung was reinflated and the animal was moved to a prone position until spontaneous breathing occurred.

Fig. 1. ECG of sham (a) and myocardial infarction (b) group.

Assessment of heart function

Twenty-eight days after MI, the rats were anesthetized with 10% chloral hydrate and placed on a pad. A micromanometer catheter was introduced into the right carotid artery and advanced across the aortic valve into the left ventricular cavity to record left ventricular pressures. Left ventricular end-diastolic pressure (LVEDP) and the maximum rates of contraction (dp/dt\textsuperscript{max}) and relaxation (dp/dt\textsuperscript{min}) were derived from the left ventricular pressure pulse (Van 2004). Each hemodynamic evaluation was completed within 20-30 minutes. At the termination of the functional study, the heart was removed and weight was obtained.

Cell dissociation

Single cardiomyocytes (left ventricle cell) of the rat heart were isolated by an enzymatic dissociation method (Ohmoto-Sekine 1999). The heart was removed from the open chest of rats anesthetized with 10% chloral hydrate and mounted on a modified Langendorff perfusion system for retrograde perfusion with Ca\textsuperscript{2+}-free Tyrode's solution; then the heart was perfused with the solution containing collagenase II and bovine serum
albumin (BSA) for about 8-10 min. After digestion, ventricular myocardium tissue was cut into small pieces in the modified Kraft-Bruhe (KB) solution (Nakaya 1993) and gently shaken to dissociate cells. All experiments were conducted at room temperature (20-22 °C).

**Patch-clamp study**

Whole-cell patch clamp recordings of transmembrane ionic currents were performed with an EPC10 amplifier (HEKA Instruments, Germany). Cardiomyocytes were placed in a perfusion chamber. Patch electrodes were fabricated from borosilicate glass with a Micropipette Puller. Its resistance was 2-4 MΩ when the electrode was filled with the pipette solution. The potential of the electrode was adjusted to zero current between the pipette solution and the bath solution immediately before seal formation. After obtaining a gigaseal, a suction pulse was applied to establish the whole-cell mode. Command pulses were delivered and data were acquired with a patch-clamp amplifier controlled by the PULSE software connected to a compute. In the end, data analysis was performed.

**Laser scanning confocal microscope analysis**

Intra-SR Ca\(^{2+}\) imaging was performed using a Leica TCS SP2 confocal microscope (Leica, Germany) in XY mode. To monitor the intra-SR Ca\(^{2+}\) levels, myocytes were loaded with 5 µM Fluo-5N AM for 3-6 h at 37 °C. When measured, Fluo-5N was excited by 488 nm laser line, and fluorescence was acquired at wavelengths of 500-530 nm.

For quantitative studies, the temporal dynamics in fluorescence were expressed as \(\Delta F/F_0 = (F - F_0)/F_0\), where \(F\) represents fluorescence at time \(t\) and \(F_0\) stands for baseline fluorescence.

**Real-time quantitative RT-PCR determination of Ca\(^{2+}\) handling genes**

The mRNA levels of RyR2, calmodulin, sorcin, calsequestrin, SERCA2a, PLB, Cav1.2 and NCX were measured using real-time quantitative RT-PCR. Total RNA was extracted using the TRIzol reagent and purified to remove any contaminating genomic DNA by on-column DNase digestion. First-strand synthesis and real-time amplification were performed using the Platinum qRT-PCR ThermoScript One-Step System (Invitrogen) and with the TaqMan Assays-on-Demand primer/probes pairs specific for RyR2, calmodulin, sorcin, calsequestrin, SERCA2a, PLB, Cav1.2 and Actin. Standard amplification curves were generated from Actin. Optimal PCR curves were observed within 40 cycles using the real-time quantitative PCR system (FTC2000, Canada). Three sets of RNA isolations were evaluated and each measurement was performed in triplicate. The threshold value (Ct) was set with the amplification-based threshold algorithms from Stratagene. Actin expression of each sample was used as endogenous control. All primer sets are listed in Table 1.

**Immunoprecipitation and western blotting analysis**

RyRs protein was immunoprecipitated from 500 µg (total protein) samples by overnight incubation with mouse anti-RyR (Jayaraman 1992) antibody, followed by incubation with protein G PLUS-Agarose at 4 °C for an additional 1 h, and then the beads were washed three times with ice-cold buffer, each time for 10 min. The proteins bound to the Sepharose beads were then solubilized by the addition of Laemmli’s sample buffer plus 5 % (v/v) β-mercaptoethanol and boiled for 5 min. The samples were separated on sodium dodecyl sulphate gel electrophoresis (SDS/PAGE) (6 %

separation gel for RyR2, 15% separation gel for calmodulin, 12% separation gel for sorcin, 10% separation gel for calsequestrin, PP1 and PP2A). The SDS/PAGE-resolved proteins were transferred to nitrocellulose membranes at 30 mA for 16.5 h at 4 °C. The nitrocellulose membranes containing the transferred proteins were blocked for 1 h with PBS containing 0.5% Tween 20 and 5% (w/v) skimmed milk. The blocked membranes were then incubated with respective antibodies (1:1,000) (Wehrens 2003) for 1 h and washed three times for 5 min in PBS containing 0.5% Tween-20. The membrane was then incubated with the appropriate horseradish peroxidase-conjugated secondary antibody (1:5,000) for 1 h. After washing three times for 5 min each in PBS containing 0.5% Tween 20, these proteins were detected by enhanced chemiluminescence (ECL). Band densities were quantified by using LabWorks4.6 software (PerkinElmer). The level of NCX, Cav1.2, SERCA2a, PLB, PLB-S16 and PLB-T17 protein were also determined by immunoblot analysis. Cell lysate proteins were subjected to SDS 6%, 8% and 12% PAGE, blotted onto nitrocellulose membranes, and probed with anti-NCX1, anti-DHPRα1, anti-SERCA2a, anti-PLB and anti-PLB-S16, anti-PLB-T17, respectively.

**Drugs and solutions**

Fluo-5N was purchased from Biotium; TRIzol Reagent was purchased from Invitrogen Life Technologies (USA), Protein G PLUS-Agarose (lot number #C1009) and Normal Mouse IgG (lot number #I2208) were purchased from Santa Cruz, RyR antibody (lot number 713354), calmodulin antibody (lot number 663553), sorcin antibody (lot number 716045), calsequestrin antibody (lot number 399596), NCX1 antibody (lot number 686846), SERCA2a antibody (lot number 629766), PLB antibody (lot number 669574), PLB-S16 antibody (lot number 647789) and DHPRα1 antibody (lot number 717054) were purchased from Abcam, PLB-T17 antibody (lot number #C2009) was purchased from Abcam, PLB-S16 antibody (lot number #I2208) were purchased from Millipore; and collagenase II was purchased from Worthington (USA). All other reagents were purchased from Sigma (USA). The composition of the Ca\textsuperscript{2+}-free Tyrode's solution was (in mM) NaCl 135, KCl 5.4, MgCl\textsubscript{2} 1.0, NaH\textsubscript{2}PO\textsubscript{4} 0.33, glucose 5.0, and HEPES 5.0 (pH 7.3). The composition of the digestion solution was Ca\textsuperscript{2+}-free Tyrode's solution 25 ml, collagenase II 15 mg, BSA 50 mg, and 72 mmol/l CaCl\textsubscript{2} 20 μl. The composition of the modified Kraft-Bruhe (KB) solution was (in mM) KOH 80, L-glutamic acid 50, KCl 30, taurine 20, KH\textsubscript{2}PO\textsubscript{4} 30, MgCl\textsubscript{2} 3, glucose 10, EGTA 0.5, and HEPES 5.0 (pH 7.3). The external solution contained (in mM) NaCl 133.5, CsCl 4.0, CaCl\textsubscript{2} 1.8, MgCl\textsubscript{2} 1.2, HEPES 10, and glucose 11.1 (pH 7.3). Patch pipettes were filled with a solution that contained (in mM) CsCl 120, TEA-Cl 10, Na\textsubscript{2}ATP 5, MgCl\textsubscript{2} 6.5, Tris GTP 0.1, and HEPES 10 (pH 7.2).

**Statistical analysis**

Data are expressed as mean ± S.E. for all the experiments. Statistically significant differences between the HF and the control were determined by \( t \)-test. The statistical significance was set at \( *P<0.05 \) and \( **P<0.01 \).

**Results**

**Characterization of cardiac function**

According to the experiment, infarct size of rat heart is more than 40% and afteroperation mortality is 20% in HF group. Hemodynamic responses were

assessed in control rats and HF rats (Table 2). There was a significant decrease in the maximal change of systolic pressure over time (dp/dt_{max}) in HF rats (2,174.42±229.02 mmHg/s, n=18) compared with control rats (4,237.82±215.39 mmHg/s, n=10, P<0.01). Furthermore, there was a significant increase in heart weight (HW) divided by body weight (BW) in HF rats (4.62±0.25, n=18) compared with control rats (2.97±0.28, n=10, P<0.01) (Table 2).

**Measurement of L-type calcium current**

It showed representative traces of I_{Ca,L} recorded during a depolarizing step from −40 to +10 mV in cardiac myocytes from control and failing hearts. The amplitude of I_{Ca,L} was reduced in HF myocytes (current/capacitance: 1.01±0.08, n=20 cells from ten HF hearts) compared with control (2.18±0.09, n=18 cells from nine control hearts, P<0.01) (Figure 2a-c).

**Measurement of SR Ca^{2+} content**

Isolated cardiomyocytes were loaded with Fluo-5N and SR Ca^{2+} content can be measured directly. The images showed that the SR Ca^{2+} content was dramatically reduced in HF myocytes (Figure 3a-d). There was a significant decrease in spatial averages (ΔF/F_{0}) in HF (26.4±1.8, n=12 cells from six HF hearts) compared with control (49.2±2.9, n=10 cells from five control hearts, P<0.01) (Figure 4a-c).

**mRNA expression of Ca^{2+} handling genes**

Real time quantitative RT-PCR was performed to determine the relative mRNA expression pattern of RyR2, calmodulin, sorcin, calsequestrin, SERCA2a, PLB, Cav1.2 and NCX. We found that the mRNA expression of RyR2 and PLB failed to alter in HF compared with control group (P>0.05). The down-regulation of calmodulin, sorcin, calsequestrin SERCA2a, Cav1.2 and NCX was established by RT-PCR to be
significant ($n=6$, $P<0.01$) relative to the control, respectively (Figure 5a-h).

Expression of SR proteins

Immunoblot analyses were performed to determine the contents of the major SR Ca$^{2+}$ handling proteins RyR2, calmodulin, sorcin, calsequestrin, PP1, PP2A, NCX, SERCA2a, PLB, PLB-S16, PLB-T17 and Cav1.2 in control and HF group. The association of calmodulin, sorcin, calsequestrin, PP1, PP2A with RyR2 were determined firstly by immunoprecipitation using an anti-RyR antibody, and followed by immunoblotting with respective antibody. Compared with channel complexes from control rat, the expression of RyR2 and PLB failed to alter ($n=6$, $P>0.05$) (Figure 6a,i,7a,i), whereas calmodulin, sorcin, calsequestrin, PP1 and PP2A contents were significantly reduced from HF rat ($n=6$, $P<0.01$) (Figure 6b-f, 7b-f). Furthermore, the expression of NCX, SERCA2a, PLB-S16, PLB-T17 and Cav1.2 were decreased ($n=6$, $P<0.01$, $P<0.05$) (Figure 6g,6h,6j,6k,6l, 7g,7h,7j,7k,7l).

Discussion

Numerous studies have suggested that abnormal Ca$^{2+}$ homeostasis may play a key role in HF. Calcium homeostasis is the maintenance of stable intracellular calcium levels during systole and diastole, and is governed by numerous proteins that regulate the flow of calcium ions among the extracellular space, cytoplasm, and intracellular stores. Many studies have shown that contractile dysfunction in HF is attributable largely to reduced myocyte Ca$^{2+}$ transients that ultimately arise from decreased SR Ca$^{2+}$ load (Pogwizd et al. 2001, Hobaia and O’Rourke 2001, Lindner et al. 1998).

Although recent advances in the field of molecular biology have shed light on the close relationship between Ca$^{2+}$ cycling abnormalities and the progression of HF, the exact molecular causes of HF are still uncertain. The aim of our study was to determine (1) L-type calcium current (LTCC); (2) SR Ca$^{2+}$ content; (3) expression of RyR2 and RyR2 interacting proteins including calmodulin, sorcin, calsequestrin, PP1 and PP2A; (4) expression of SERCA2a, PLB, PLB-S16 and PLB-T17; (5) expression of Cav1.2; and (6) expression of NCX.

In our study, we found that a significant reduction in the SR Ca$^{2+}$ content (HF: $\Delta F/F_0 = 26.4\pm1.8$, $n=12$ cells from six HF hearts, control: $\Delta F/F_0 = 49.2\pm2.9$, $n=10$ cells from five control hearts, $P<0.01$). The alteration in SR Ca$^{2+}$ content is considered to be hallmarks of HF.

Depolarization of the plasma membrane by an incoming action potential activates voltage-gated L-type Ca$^{2+}$ channels (DHPR or Cav1.2) in plasma membrane invaginations called T-tubules. In the heart, Cav1.2 activation results in a plasma membrane Ca$^{2+}$ influx current, which triggers RyR2 activation and SR Ca$^{2+}$ release, referred to as Ca$^{2+}$-induced Ca$^{2+}$ release (CICR). The efficiency of the trigger (the size of the inward Ca$^{2+}$ current) needed to cause Ca$^{2+}$ release from the SR has been termed excitation-contraction coupling (E-C coupling) gain. In many cases of HF, the E-C coupling gain seems to be reduced by a functional defect in LTCC, an increase in the space between LTCC and RyR, a decrease in SR Ca$^{2+}$ and/or an abnormality in the

![Fig. 4. Plots of fluorescence profiles in control (a) and HF myocytes (b). The average amplitudes ($\Delta F/F_0$) were 49.2±2.9 in control and 26.4±1.8 in HF myocytes (c), ($P<0.01$, $n=10$ cells from five control hearts, $n=12$ cells from six HF hearts)
channel-gating property of RyR. Not only the amount of Ca\(^{2+}\) released for a given Ca\(^{2+}\) release trigger but also the rate of Ca\(^{2+}\) release may be important for the contractility of the myofilaments. The present study shows that the expression of Cav1.2 seems to be reduced, which lead to the decreased amplitude of ICa·L.

In mammalian cardiac muscle, the SR is the major source of the calcium that activates contraction. Calcium is released from the SR through a channel known as the RyR. The approximately 4,000 amino acid large N-terminal domain of the RyR is exposed to the junctional cytosolic compartment and serves as a scaffold for protein-protein interactions and channel modulation (Bers 2004). The RyR binds with many accessory proteins, such as calmodulin, FKBP12.6, PKA, PP1 and PP2A, producing a huge macromolecular complex. They act as an important modulator for maintaining normal Ca\(^{2+}\) cycling. Defective regulation of channel gating by these key proteins may render the channel leaky. Modulation of the RyR is critical to survival, and consequently influenced by multiple regulatory mechanisms, include PKA-dependent phosphorylation of RyR (Xiao et al. 2005) and Ca\(^{2+}\)-Calmodulin dependent protein kinase (CaMKII) phosphorylation of RyR (Guo et al. 2006), the mechanism of latter is not known. The RyR does not exist in isolation but is coupled to other proteins, include FKBP12.6, junctin, triadin and calsequestrin (Wehrens et al. 2003, Terentyev et al. 2007), which may affect its open probability (P₀).

In our previous study, we demonstrated that the expression of RyR2 failed to alter, while the expression of FKBP12.6 associated with RyR2 was significantly reduced in HF rat. The present study explored the alterations in regulation and function of the RyR2 macromolecular complex that occur in HF. In the heart, the majority of phosphatase activity is attributed to type 1 protein

![Fig. 5. Relative expression of Ca\(^{2+}\) handling genes RyR2 (a), SERCA2a (b), PLB (c), Cav1.2 (d), NCX (e), Calsequestrin (f), Calmodulin (g) and Sorcin (h) in control and HF myocytes.](image-url)
phosphatase PP1, and type 2 phosphatases, PP2A and PP2B. Among these phosphatases, PP1 is of particular importance since it has been implicated as an important negative regulator of cardiac function. In fact, alterations in its levels and activity play a major role in the pathogenesis of heart failure. In the immunoprecipitated RyR2 complex in HF, we found reduced PP1 and PP2A. These changes would explain the enhanced RyR2 phosphorylation at sites of PKA action. We also found reduced calmodulin, sorcin and calsequestrin. Calmodulin inhibits RyR2 open probability at physiological [Ca\(^{2+}\)] (Marx et al. 2000), and the lower calmodulin associated with the RyR2 in HF here may contribute to increased SR Ca\(^{2+}\) leak in HF. Sorcin is a cytosolic Ca\(^{2+}\)-binding protein that associates with RyR2 and may facilitate channel closure. Reduced expression of sorcin may also contribute to increased SR Ca\(^{2+}\) leak in HF. Calsequestrin is a major intra-SR Ca\(^{2+}\) binding protein. It forms a complex with the RyR2, triadin, and junction. In addition to its Ca\(^{2+}\) buffering action, calsequestrin has been shown to regulate RyR2 function as a luminal Ca\(^{2+}\) sensor of RyR2 (via protein-protein interactions involving triadin and junctin) (Györke et al. 2004). Reduced calsequestrin may decrease the open probability of RyR, which result in decreased SR Ca\(^{2+}\) release in HF.

Another mechanism for restoring cytosolic calcium to diastolic levels is through reuptake of calcium by the SR via the SERCA2a, which (to some extent) competes with the NCX for cytoplasmic calcium. Some research has demonstrated that the SR Ca\(^{2+}\) uptake rate was not significantly altered and the expression of SERCA2a was unchanged in HF myocytes (Hasenfuss 1998). We found, however, the expression of SERCA2a was decreased in HF rat compare with control rat. It is also a critical factor determining the reduced SR Ca\(^{2+}\) content in HF. Calcium reuptake via SERCA2a is significantly influenced by phosphorylation (PLB), a protein that, in its unphosphorylated form, inhibits SERCA2a, while in the phosphorylated state favors SERCA2a activity. PKA-dependent phosphorylation of PLB (PLB-S16) is the likely mechanism of accelerated relaxation associated with catecholamines (Li et al. 2000). CaMKII can also accelerate SR calcium reuptake by phosphorylation of PLB (PLB-T17) and, possibly, by a mechanism that does not require PLB (Desantiago et al. 2002). In the present study, the expression of PLB failed to alter, while the expression of PLB-S16 and PLB-T17 were reduced in HF, which leads to inhibition of SERCA2a. Furthermore, the protein expression of SERCA2a relative to PLB was diminished in HF. This ratio (the protein expression of SERCA2a relative to PLB) also indicates the extent of Ca\(^{2+}\) pump inhibition, and hence the basal level of SERCA2a activity is at a
lower level in failing hearts than in normal hearts.

On the other hand, the cardiac Na⁺/Ca²⁺

exchanger (NCX1) is almost certainly the major Ca²⁺
extrusion mechanism in cardiac myocytes, although the

driving force for Ca²⁺ extrusion is quite small. The

functional consequences of NCX overexpression in heart

failure are controversial (Litwin and Bridge 1997). Previous studies in failing myocytes from the rabbit indicate that NCX overexpression is responsible for a reduction in sarcoplasmic reticulum Ca²⁺ content and contractile dysfunction (Pogwizd et al. 2001). Using a canine model of cardiac hypertrophy, Sipido et al. (2000) showed that enhanced NCX function resulted in improved contractility. More recent studies in human failing myocytes suggest that NCX may be responsible for maintaining [Ca] during diastole (Piacentino et al. 2003). Assessment of this controversy requires that two points be considered: species-dependence of NCX function and the degree of hypertrophy and/or associate failure. We found the expression of NCX was decreased in our experiment. This may possibly be explained by differences in the stage and/or severity of the HF. Our hypothesis is that the downregulation of NCX fails to maintain function in late stages of heart failure. Further investigation is still needed to clarify the role of NCX and other SR Ca²⁺ handling proteins.

In conclusion, systolic SR reduced Ca²⁺ release and diastolic SR Ca²⁺ leak (due to defective protein-protein interaction between RyR2 and its associated proteins) along with reduced SR Ca²⁺ uptake (due to down-regulation of SERCA2a, PLB-S16 and PLB-T17), abnormal Ca²⁺ extrusion (due to down-regulation of NCX) and defective CICR (due to down-regulation of Cav1.2) could contribute to heart failure.

Conflict of Interest

There is no conflict of interest.
