Summary

The aim of the present research was to study the uptake of DHEAS, and to establish the intracrine capacity of human platelets to produce sex steroid hormones. The DHEAS transport was evaluated through the uptake of [³H]-DHEAS in the presence or absence of different substrates through the organic anion transporting polypeptide (OATP) family. The activity of sulfatase enzyme was evaluated, and the metabolism of DHEAS was measured by the conversion of [³H]-DHEAS to [³H]-androstenedione, [³H]-testosterone, [³H]-estrone and [³H]-17 β -estradiol. Results indicated the existence in the plasma membrane of an OATP with high affinity for DHEAS and estrone sulphate (E₁S). The platelets showed the capacity to convert DHEAS to active DHEA by the steroid-sulfatase activity. The cells resulted to be a potential site for androgens production, since they have the capacity to produce androstenedione and testosterone; in addition, they reduced [³H]-estrone to [³H]-17 β -estradiol. This is the first demonstration that human platelets are able to import DHEAS and E₁S using the OATP family and to convert DHEAS to active DHEA, and to transform E₁S to 17 β -estradiol.

Key words

Platelet • Intracrine • Steroid sulfatase • DHEAS

Introduction

Platelets play a crucial role in the development of arterial thrombosis and other pathophysiologicals leading to clinical ischemic events. In human, the incidence of adverse thrombotic events increases with age, and many studies suggest that low sex steroids hormones level accelerates age-related pathogenic changes in vascular and haemostatic systems (Wilkerson *et al.* 2002). In women, at menopause the deficiency of sex steroids hormones accelerates age-related pathogenic changes in vascular and haemostatic systems.

The effect of sex hormone on platelet function has been investigated for years, but conflicting results have been reported. Treatment of platelets with estrogen *in vitro* has not always produced results consistent with estrogens *in vivo* prothrombotic activity. One variable that confounds *in vitro* assays of platelet aggregation is the intrinsic effect of endogenous estrogens within platelets (Leng and Bray 2005). Some studies show that there are significant differences in the concentration of 17 β -estradiol between the inside and outside of platelets (Nakano *et al.* 1998, Sarabia *et al.* 2008). The ratio of platelet to plasma estradiol concentrations in men, premenopausal and postmenopausal women was 7.0, 2.8 and 5.3 fmol per platelet x 10⁹/pmol l⁻¹ plasma, respectively. The mechanism by which the internal concentration is increased had not been clarified; it has been suggested that some transport exist in platelet to increase the levels of sex hormones in the intraplatelet pool (Sarabia *et al.* 2008). Nevertheless, similar to what it happens in peripheral tissue, the platelets might synthesize steroids hormones.

Human, along with other primates, are unique among animal species in having adrenals that secrete

large amounts of precursor steroids like dehydroepiandrosterone (DHEA) and especially DHEA-sulfate (DHEAS). The plasma levels of DHEA in human are 100 to 500 times higher than testosterone and 1,000 to 10,000 higher than estradiol (Labrie *et al.* 2005). DHEA can be converted downstream to sex steroids, thereby having its role as a precursor for human sex steroid biosynthesis (Labrie *et al.* 2005). Many reports have shown evidences that DHEA/DHEAS could play a protective role in the pathogenesis of atherosclerosis and coronary heart disease (Porsova-Dutoit *et al.* 2000, Triveli *et al.* 2001). However, the mechanism of action of these steroids is not clear. Peripherally, DHEA appears to exert its primary effect through its estrogenic and androgenic metabolites because a unique DHEA receptor has not been characterized (Susan *et al.* 2012). The direction of conversion of DHEA defines its biological action in target tissues and depends on the tissue-specific expression of the steroidogenic enzymes. This system illustrates the concept of intracrinology involving activation, action, and metabolism of steroids within one and the same peripheral target cell (Labrie *et al.* 2001).

While DHEA is highly hydrophobic, DHEAS is hydrophilic and requires active transport to enter the cell. Many studies in human tissues have implicated several members of the organic anion transport polypeptide (OATP) family as responsible for DHEAS influx transport (Hagenbuch and Meir 2003, Ugele *et al.* 2003). Once in the cell, DHEAS may be activated to DHEA following hydrolysis of sulfate group by the microsomal enzyme steroid sulfatase (STS) (Reed *et al.* 2005). Vice versa, DHEA can be inactivated *via* sulfonation to DHEAS by cytosolic DHEA sulfotransferase. Thus, tissue-specific expression and activity of the components of this "DHEAS/DHEA shuttle" system will determine intracellular bioavailability of DHEA.

There are experimental evidences showing human platelets involvement in steroid-metabolism; for instance, they can convert androstenedione to potent androgens (Milewich and Whisnant 1982). Also, human platelets are a site of estrogens production since they are able to convert estrone sulfate to estrone (Soliman *et al.* 1993). However, it has not been investigated whether platelet cells are sites of conversion of DHEAS to DHEA, a potential precursor for the synthesis of steroids. In addition, it is not clear whether they possess aromatase activity required for the conversion of androgens into estrogens. This study aimed to determine the uptake of DHEAS, and to establish the intracrine capacity of human

platelets to produce sex steroid hormones.

Materials and Methods

Steroids and chemical

For the enzyme assays, we used [1,2,6,7-³H]-dehydroepiandrosterone-sulphate (84 Ci/mmol), [1,2,6,7-³H]-DHEA (74 Ci/mmol), [1 β -³H]-androstenedione (24.3 Ci/mmol), [6,7-³H]-estrone-sulfate (43.5 Ci/mmol), all obtained from Perkin-Elmer Life Science (Boston, MA). Unlabeled steroids were purchased from Sigma-Aldrich. The bromosulphophthalein (BSP) from Applichem-Germany; all other chemicals and solvents were from Merck (Darmstadt, Germany).

Isolation of human platelets

Platelet-rich plasma (PRP) was prepared by differential centrifugation (180 x g, 15 min, 23 °C) of fresh whole human blood drawn into acid-citrate anticoagulant (1:9 v/v). The PRP-derived platelet concentrates (PCs) were obtained by centrifugation at 1000 x g for 10 min at 20 °C. The freshly prepared PCs were washed free of plasma components twice with Ca²⁺ free Tyrode's buffer (137 mM NaCl, 2.9 mM KCl, 12 mM NaHCO₃, 0.42 mM Na₂HPO₄, 5 mM HEPES, 2 mM MgCl₂ and 5.5 mM glucose pH 7.4), according to the method described by Mustard *et al.* (1972). Washed platelets were resuspended in Tyrode's buffer and platelet concentrations were determined electronically with Coulter counter and adjusted to ~ 5 x 10⁸ platelets/ml.

DHEAS transport in platelets

Washed platelets (3 x 10⁸) were resuspended in 1 ml of uptake buffer (Tyrode's buffer containing [³H]-DHEAS). Then, platelets were incubated at various periods of time with constant shaking at 37 °C, and the uptake was terminated by addition of 1 ml of ice-cold Tyrode's buffer followed by rapid filtration under reduced pressure through Whatman GFC glass fiber filters pre-washed with uptake buffer. The filters were rapidly washed with cold assay buffer (3 times, 1 ml each). The cell-associated radioactivity was determined by transferring the dried filters to scintillation vials and measuring radioactivity by liquid scintillation.

For inhibition studies, uptake of [³H]-DHEAS was measured in the presence of unlabeled compounds such as sulfobromophthalein (BSP; 0-50 μ mol/l), a specific inhibitor of the OATP family, or in the presence of an excess of estrone sulfate (50 μ mol/l) or DHEAS

(50 $\mu\text{mol/l}$); the samples were incubated at 37 °C for 5 min.

Assay of sulfatase activity

The activity of STS was measured according to the method of Steckelbroeck *et al.* (2004). In brief, in a final volume of 200 μl , aliquots of platelets ($\sim 1.5 \times 10^8$ platelets) were incubated at 37 °C with 0.5 μM DHEAS and 300,000 dpm of [^3H]-DHEAS for different times, with constant shaking. The reaction was terminated by adding 2 volumes of 0.1 N NaOH, and DHEA was extracted with 3 ml of toluene. The radioactivity in the toluene extract was measured in a 0.5 ml aliquot with a liquid scintillation counter. Spontaneous DHEAS conversion and background radioactivity were subtracted from each experimental assay tube. The metabolite was identified by TLC-silica gel using the system toluene-ethanol-water (90:9.5:0.5) and appropriate standard (Wong and Keung 1997).

Metabolism of [^3H]-DHEAS

Platelets ($2-3 \times 10^8$ platelet) were incubated for 3 h at 37 °C in 0.2 ml Tyrode's buffer containing 0.5 μM DHEAS and 4×10^5 dpm of [^3H]-DHEAS. At the end of the incubation period, 50 μg of the nonradioactive carrier steroids androstenedione (A), testosterone (T), estradiol (E_2) and estrone (E_1) were added to each sample. The reaction was stopped with 1.5 ml of acetone-ethyl acetate (1:2.5; v/v) and the organic supernatant layer was removed. A portion (1 ml) of the extract was evaporated to dryness, and the residue were then dissolved in 100 μl of dichloromethane and the yield of metabolites measured after separation by chromatography,

The steroids in the extract were separated by TLC on silica gel using xylene- ethylacetate-chloroform (40:15:45, v/v) which gives good separation of T, A and E_1 (Rf: 0.26, 0.55 and 0.79, respectively; Rf is the distance traveled by the compound divided by the distance traveled by the solvent). The localization of steroids were visualized and identified by their chromogenic properties after spraying with 5 % (v/v) sulphuric acid in methanol and heating on a hot plate (Heftmann *et al.* 1996).

Control incubations containing [^3H]-DHEAS in Tyrode's buffer but without platelets, were processed in a similar manner.

Metabolism [^3H]-estrone-sulfate

Platelets ($2-3 \times 10^8$ platelet) were incubated for

3 h at 37 °C in 0.2 ml Tyrode's buffer containing 0.5 μM E_1S and 5×10^5 dpm of [^3H]- E_1S . At the end of the incubation period, 50 μg of the nonradioactive carrier steroid E_1 and E_2 were added to each sample. The reaction was stopped with 2 ml of ether and the organic supernatant layer was removed. A portion (1.5 ml) of the extract was evaporated to dryness, and the residue dissolved in 100 μl of acetonitrile-water (45:55, v/v) and further separated on Sephasil C reverse-phase chromatography column connected Merck-Hitachi System. Fractions containing estrone and 17 β -estradiol were dissolved in scintillation liquid and radioactivities were measured.

Aromatase activity assay

Aromatase activity was quantified by the stereospecific loss of the tritium atom of the [1β - ^3H]androstenedione substrate in the aromatization reaction. The conversion rate was determined by the isolation and quantification of tritiated water (Lephart *et al.* 1991). Aliquots of washed platelets ($0.5-2 \times 10^8$ platelets) were incubated with 200 nM [1 - ^3H]-androstenedione to make a final volume of 200 μl . A portion of the aqueous phase was mixed with an equal volume of 5 % charcoal-0.5 % dextran suspension, centrifuged for 30 min at 2000 x g, and quantified by liquid scintillation counting. Background values for $^3\text{H}_2\text{O}$ released in the absence of cells were subtracted from each point.

Statistical analyses

Data are expressed as means \pm S.D. The significance of differences between the mean values was determinate by Student's t test, and a p value of less than 0.05 was considered statistically significant.

Results

DHEAS transporters assay

This assay was performed to investigate whether DHEAS transport is OATP-mediated in these cells. Then, the cis-inhibitory effect of a variety of non-radioactive conjugated steroids and OATP substrates on DHEAS uptake was examined.

We first incubated the platelets with [^3H]-DHEAS at increasing OATP-specific substrate concentrations BSP (0-50 $\mu\text{mol/l}$) over a period of 5 min. As shown in Figure 1, the uptake revealed a decreased response with increased concentrations of BSP.

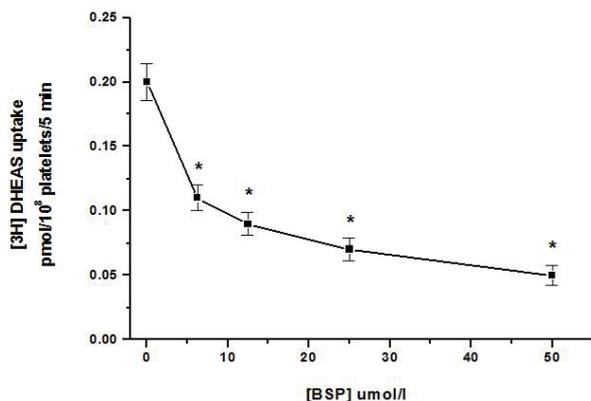

Fig. 1. Human platelets DHEAS uptake: Inhibitory effect of sulfobromophthalein (BSP). The uptake was measured after 5 minutes of platelets incubation with [³H]-DHEAS in the presence of increasing concentrations of BSP (0-50 μmol/l). Data represent the mean ± S.D. for three experiments. * P<0.05 compared with control without BSP.

We also examine the substrate selectivity of the transport system. The uptake of [³H]-DHEAS was strongly inhibited by common OATP substrates, BSP (50 μmol/l), DHEAS (50 μmol/l) and estrone sulfate (50 μmol/l) (% of control; Fig. 2).

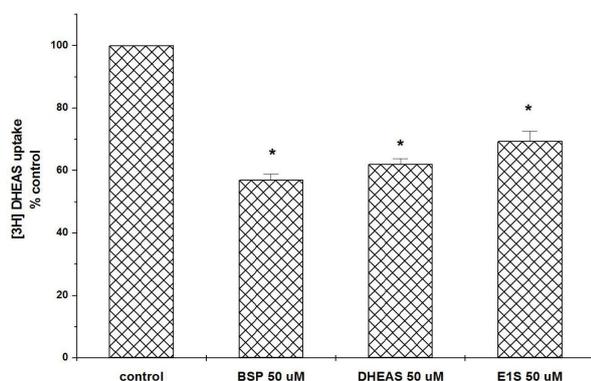

Fig. 2. The substrate selectivity of OATP system in human platelets. The uptake was measured after 5 minutes of platelets incubation with [³H]-DHEAS in the presence of BSP (50 μmol/l), DHEAS (50 μmol/l) or estrone sulfate (50 μmol/l). Data represent the mean ± S.D. for three experiments. * P<0.05 compared control.

As described, estradiol-β-glucuronide is not a substrate of OATPB, and therefore is not able to be transported into the cells; in the present study we evaluated the uptake of [³H]-estradiol-β-glucuronide in human platelets. No uptake of this labelled steroid was observed (100±6.4 % control vs. 98.2±8.7 % [³H]-estradiol-β-glucuronide), indicating that the OATP present in human platelets have the characteristics of OATPB.

Conversion of DHEAS to DHEA in human platelets

Platelets contain aryl sulfatase activity, as indicated by the conversion of [³H]-DHEAS to [³H]-DHEA in the order of 9.6±0.54 pmol/h • 10⁸ platelets. There was a linear relationship between the amount of DHEA produced and platelet concentration up to 3.0 × 10⁸ platelets (data not-shown), and the hydrolysis of [³H]-DHEAS was observed to proceed linearly with incubation times up to 3 h (Fig. 3).

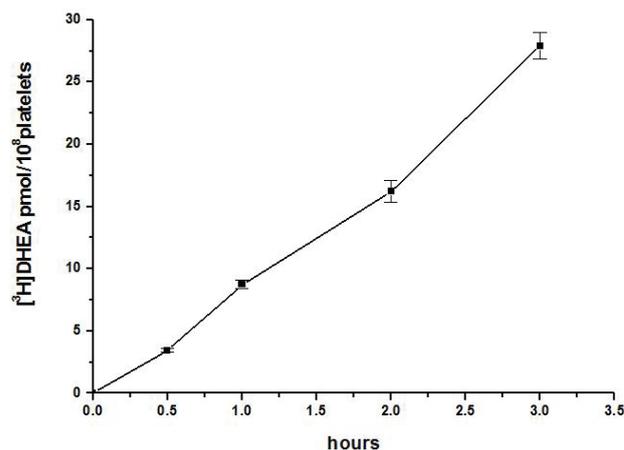

Fig. 3. Sulfatase activity through the production of [³H]-DHEA from [³H]-DHEAS by human platelets. Aliquot of platelets (~ 1.5 × 10⁸ platelets) were incubated with 0.5 μM and 300,000 dpm of [³H]-DHEAS for different times at pH 7.4 and 37 °C. Data represent the mean ± S.D. (n=4 experiments).

Metabolism of [³H]-DHEAS

By adding [³H]-DHEAS to platelets, we sought to investigate whether human platelets are capable of using DHEAH as a substrate for local steroidogenesis. The metabolites produced per 10⁸ platelets (n=3) in 3 h incubation were identified as androstenedione (3.3±0.8 pmol) and testosterone (2.1±0.5 pmol).

Aromatase activity assay

The potential capacity of human platelets to produce estrogens was assessed by the incorporation of tritium from [1-³H]-androstenedione into [³H]-water. In the presence or absence of platelet the radioactivity of [³H]-water was 430±40 dpm/h • 10⁸ platelets and 590±210 dpm/h • incubated, respectively. This value represents the mean ± S.D. of six independent determinations. In the presence of a specific nonsteroidal aromatase inhibitor (letrozole, 10 μM), the incorporation of radioactivity into [³H]-water was not affected; 465±51 dpm/h • 10⁸ platelets in the control versus 446±39 dpm/h • 10⁸ platelets in the presence of letrozole.

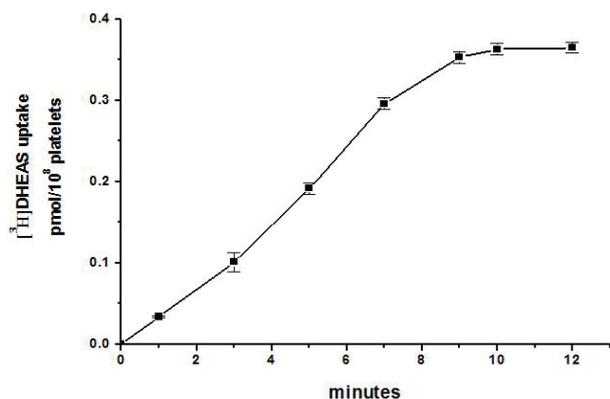

Fig. 4. Time course of the uptake of [³H]-DHEAS by human platelets. Uptake of [³H]-DHEAS over 10 minutes was measured at 37 °C in the Tyrode's buffer at pH 7.4. Each result represent the mean ± S.D. (n=7 experiments).

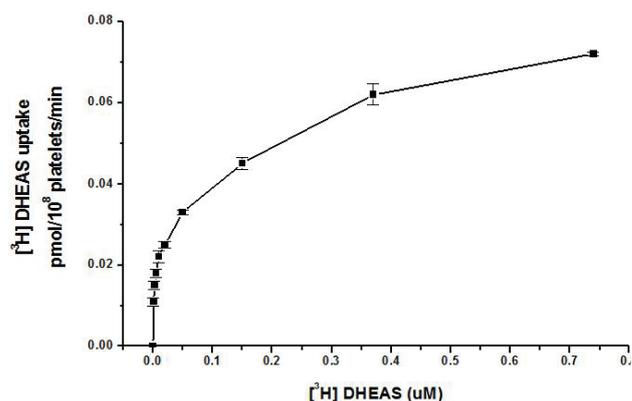

Fig. 5. Concentration dependence of [³H]-DHEAS uptake by human platelets. The uptake of [³H]-DHEAS was measured after 5 minutes of platelet incubation with various concentrations of [³H]-DHEAS from 1.2 nM to 0.8 μM at pH 7.4. Data represent the mean ± S.D. (n=4).

Conversion of [³H]-E₁S to estradiol

The role of E₁S as precursor of estradiol in platelets was analyzed. An amount of 10⁸ platelets produced in 3 h incubation 3.1±0.7 pmol 17β-estradiol (n=4).

Transport of DHEAS

To analyze the transport of DHEAS in human platelets, we evaluated the uptake of [³H]-DHEAS for different periods of time (0-12 min). We observed that [³H]-DHEAS uptake increased linearly for 7 min and reached a steady state between 9 and 12 min (Fig. 4). The initial rate for the uptake of DHEAS concentrations (0.0012 μM to 0.74 μM) was then determined (Fig. 5). Kinetic analysis revealed a saturable uptake mechanism.

Discussion

Circulating blood platelets are anucleated cells that retain small amounts of megacaryocyte mRNA_(s) and fully functional proteins (Gnatenko *et al.* 2003, McRedmond *et al.* 2004). The main interest of the present study was to investigate platelet STS in the context of DHEAS carrier, as well the possible *de novo* biosynthesis of androgens and estrogens. The results of our studies confirm that STS and DHEA metabolizing enzymes are present in human platelets (Soliman *et al.* 1993). Additionally, our data demonstrate strong interaction of organic anionic polypeptide transporters (OATP)-mediated uptake of DHEAS and estrone-sulfate.

Although circulating blood platelets import a variety of free and conjugate steroids, the most important precursor appears to be DHEAS, which circulates at much higher concentration than free DHEA, gonadal

steroids, and cortisol (Labrie *et al.* 2001). We did not characterize the transporter; however, our results clearly indicate the existence in the membrane of platelets of an OATP with high affinity for DHEAS and estrone sulfate. Supporting evidences for the presence of such transport system include 1) a saturable uptake kinetics, 2) significant time dependence for the uptake of DHEAS, and 3) inhibition of the uptake in the presence of structural analogs. The fact that no uptake of estradiol-17β-glucuronide by human platelets was observed, suggest that DHEAS OATP of human platelets have the characteristic of OATPB (Tamai *et al.* 2001). This type of transporters are present in a broad range of tissues, where OATP2B1 is the predominant mediator of DHEAS (Kullak-Ublick *et al.* 2001, Pizzagalli *et al.* 2003). Interestingly, it has been recently demonstrated that human platelets express high abundance of OATP2B1, but not OATP1B1 (Niessen *et al.* 2009).

Platelet STS enzyme appears to be membrane bound. Mammalian sulfatases have been shown to be lysosomal (arylsulfatases A and B) or microsomal (arylsulfatase C), demonstrating acidic or alkaline optimal pH for their activity, respectively. This enzyme has also been found in different tissues (Miki *et al.* 2002, Reed *et al.* 2005), including leucocytes (Purohit *et al.* 1997) and platelets (Soliman *et al.* 1993, Kirk *et al.* 2001).

The presence of steroidogenic functional enzymes in platelets is strongly support by their capacity to convert [³H]-DHEAS into [³H]-androstenedione, and [³H]-testosterone. Consequently, platelets must have the enzyme 3β-hydroxysteroid dehydrogenase type 1, as indicated by the formation of androstenedione, and 17β-hydroxysteroid dehydrogenase (type 3), demonstrated

by the formation of testosterone. As mentioned before, Milewich and Whisenant (1982) previously reported on the metabolism of androstenedione by human platelets. More recently, evidence was presented showing that distinct subtypes of the steroidogenic 17 β -HSD enzymes are functionally expressed in human platelets (Gnatenko *et al.* 2005). We did not detect production of [³H]-estradiol or [³H]-estrone from [³H]-DHEA, and, furthermore, no release of ³H₂O from [¹ β -³H]-androstenedione was found, thus discarding the presence of aromatase in platelets. However, platelets have the capacity to produce estradiol by reduction of estrone.

The biological activity of sex steroid hormones occurs predominantly through binding to the intracellular steroid receptors. Human platelets express both androgen and estrogen receptors (Nealen *et al.* 2001, Jayachandran and Miller 2003), but the physiological significance of steroid hormones in their function is under debate. An important point of controversy is related to concentrations of hormone that affect platelets activation. Recently, has been demonstrated that estradiol inhibits collagen-induced platelet aggregation (Wu *et al.* 2010); concentration of estradiol at which effect were observed (5×10^{-6} - 10^{-5} mol/l) were higher than its physiological circulating level (typically 10^{-8} to 10^{-9} mol/l). The fact that such pharmacological levels of estradiol were required to inhibit platelet aggregation, suggest that intra-platelet concentration of estradiol are different from blood estradiol. Interestingly, it has been observed that the internal platelet sex hormone levels are significantly higher than concentrations of androgens and estrogens in plasma (Sarabia *et al.* 2008). The mechanism by which intra-platelet steroid concentration is increased is not clear but it has suggested that a transport system exist in platelets (Chu *et al.* 2010). However, similar to what it

happens in peripheral tissues the platelet may synthesize testosterone and estrogen.

Several studies suggest that DHEAS is a protective factor against atherosclerosis and coronary artery disease in humans, but the mechanisms involved in its biological role are not clear. DHEA administration induce vasodilatation (Williams *et al.* 2004), increases platelets cGMP production (Martina *et al.* 2006), inhibit smooth cell proliferation (Dworkin *et al.* 1986), and PAI-1 production (Beer *et al.* 1996). The *in vivo* and *in vitro* study of Jesse *et al.* (1995) demonstrated that DHEAS inhibits human platelets aggregation; importantly, in their study, it was hypothesized that DHEAS either directly inhibits platelets aggregation or that its hydrolysis occurred at the platelet surface, producing DHEA as the active steroid. Recently, it has been reported that DHEAS, but not DHEA, inhibits the *in vitro* aggregation of platelets stimulated with various agonist including thrombin, collagen and analogous of thromboxane A₂ (Bertoli *et al.* 2012).

In conclusion, taken together the above evidence and our results, for one side DHEAS/DHEA can modulate platelet function by exercising an anti-aggregating role, and for other side, the platelets can use DHEAS/DHEA or E₁S/E₁ as precursor of androgen and estrogen. The intracrine capacity of platelets indicate novel insights into the interplay between DHEAS/DHEA, platelet function and vascular disease.

Conflict of Interest

There is no conflict of interest.
